Chapter 2

Background

2.1 Drawing Monoidal Categories

A monoidal category \mathcal{C} is a category equipped with a bifunctor $\otimes : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$ and a unit object $\mathbb{1}$, such that certain associativity and unit relations hold¹. We assume that monoidal categories are strict, since all monoidal categories are monoidally equivalent to a strict one².

The morphisms of \mathcal{C} can be drawn as string diagrams, where the morphism maps from the bottom to the top. Functions that make up the morphism are drawn as tokens or boxes. For example

depicts a morphism $f : a \rightarrow b \otimes c$. For identity morphisms we drop the box and only draw a vertical line, so id_a is the diagram

The tensor product of morphisms is the horizontal concatenation of diagrams, such that strings from separate functions don't interact. For example, given $g : x \rightarrow y$, the tensor product $f \otimes g : a \otimes x \rightarrow b \otimes c \otimes y$ is drawn as

¹For more details see [Eti+15].

²See [ML98, VII.2] or [Eti+15, Thm 2.8.5]

$$\begin{array}{c} b \quad c \quad y \\ \diagdown \quad \diagup \quad | \\ \boxed{f} \quad \boxed{g} \\ | \quad | \\ a \quad x \end{array} = \begin{array}{c} b \quad c \quad y \\ \diagdown \quad | \quad \diagup \\ \boxed{f \otimes g} \\ \diagup \quad \diagdown \\ a \quad x \end{array} .$$

By convention, $\mathbb{1}$ is blank and unlabelled, and strings that would join to $\mathbb{1}$ are blank. Particularly, $\text{id}_{\mathbb{1}}$ is an empty diagram, and we have diagrams such as

$$\begin{array}{c} \boxed{f_1} \\ | \\ a \end{array} : a \rightarrow \mathbb{1} \quad \text{and} \quad \begin{array}{c} b \quad c \\ \diagdown \quad \diagup \\ \boxed{f_2} \end{array} : \mathbb{1} \rightarrow b \otimes c .$$

The compositions of morphisms is the vertical stacking of diagrams where domains and codomains match. For example, the composition $h \circ f : a \rightarrow b \otimes c \rightarrow a \otimes c$ of $f : a \rightarrow b \otimes c$ with $h : b \otimes c \rightarrow a \otimes c$ has the diagram

$$\begin{array}{c} a \quad c \\ | \quad | \\ \boxed{h} \\ \diagdown \quad \diagup \\ b \quad c \\ \diagdown \quad \diagup \\ \boxed{f} \\ | \\ a \end{array} = \begin{array}{c} a \quad c \\ \diagdown \quad \diagup \\ \boxed{h \circ f} \\ | \\ a \end{array} .$$

Before looking at our main example of a diagrammatic monoidal category, we first define some terminology.

Definition 2.1.1. For a commutative ring R , an R -linear category is a category enriched over the category of R -modules. That is, for objects a, b , the set of morphisms $\text{Hom}(a, b)$ is an R -module and the composition of morphisms is R -bilinear. A (strict) R -linear monoidal category is a monoidal category and R -linear category such that the monoidal product on morphisms is R -bilinear. [Check this, check also the order i define things](#)

Example 2.1.2. Let \mathbb{k} be a field. The category of vector spaces over \mathbb{k} , $\mathbf{Vect}_{\mathbb{k}}$, is a \mathbb{k} -linear category. This makes sense by the classical theory of linear algebra.

For a strict R -linear monoidal category \mathcal{C} , [Do we even need this?](#) the bifactoriality of $- \otimes -$ implies the following *interchange law*. For morphisms $f : a \rightarrow b$ and $g : c \rightarrow d$, $(\text{id}_b \otimes g) \circ (f \otimes \text{id}_c) = f \otimes g = (f \otimes \text{id}_d) \circ (\text{id}_a \otimes g)$. In other words the following diagram commutes.

$$\begin{array}{ccc} a \otimes c & \xrightarrow{f \otimes \text{id}_c} & b \otimes c \\ \text{id}_a \otimes g \downarrow & \searrow f \otimes g & \downarrow \text{id}_b \otimes g \\ a \otimes d & \xrightarrow{f \otimes \text{id}_d} & b \otimes d \end{array}$$

Written with string diagrams, this is

$$\begin{array}{c} b \\ | \\ \boxed{f} \\ | \\ a \end{array} \quad \begin{array}{c} d \\ | \\ \boxed{g} \\ | \\ c \end{array} = \begin{array}{c} b \\ | \\ \boxed{f} \\ | \\ a \end{array} \quad \begin{array}{c} d \\ | \\ \boxed{g} \\ | \\ c \end{array} = \begin{array}{c} b \\ | \\ \boxed{f} \\ | \\ a \end{array} \quad \begin{array}{c} d \\ | \\ \boxed{g} \\ | \\ c \end{array}$$

which holds up to deformation of the diagram.

Definition 2.1.3. A monoidal category \mathcal{C} is *generated* by finite set S_o of objects and S_m of morphisms, when all non-unit objects are a finite tensor of objects in S_o and all non-identity morphisms are a finite combination of tensors and compositions of morphisms in S_m .

Example 2.1.4. Our first example of a diagrammatic monoidal category is the *Temperley-Lieb category*. The Temperley-Lieb category \mathcal{TL} is a strict R -linear monoidal category whose objects are generated by the vertical line \mathbb{I} and morphisms generated by the cup $\cup : \mathbb{I} \rightarrow \mathbb{I} \otimes \mathbb{I}$ and cap $\cap : \mathbb{I} \otimes \mathbb{I} \rightarrow \mathbb{I}$, with relations

$$\begin{array}{c} \cup \\ \cap \end{array} = \mathbb{I} = \begin{array}{c} \cap \\ \cup \end{array}.$$

Mention that composition and tensor product is as explained above
 Some example
 Mention bubbles and specialisation to some $\delta \in R$
 Mention that these are crossingless matchings
 Comment on isotopy

2.2 Module Categories

2.3 Frobenius Objects

Something something about Many relations in categorical structures can be written in diagrammatic terms - adjunctions, monoid

Let \mathcal{C} be a (strict) monoidal category. We can define the following objects.

Definition 2.3.1. A *monoid object* in \mathcal{C} is a triple (M, μ, η) for an object $M \in \mathcal{C}$, a *multiplication* map $\mu : M \otimes M \rightarrow M$ and a *unit* map $\eta : \mathbb{1} \rightarrow M$, such that

$$\begin{array}{ccccc}
 & & M \otimes M \otimes M & & \\
 \mu \otimes \text{id}_M & \swarrow & & \searrow & \text{id}_M \otimes \mu \\
 M \otimes M & & & & M \otimes M \\
 & \searrow \mu & & \swarrow \mu & \\
 & & M & &
 \end{array}$$

and

$$\begin{array}{ccccc}
 \mathbb{1} \otimes M & \xrightarrow{\eta \otimes \text{id}_M} & M \otimes M & \xleftarrow{\text{id}_M \otimes \eta} & M \otimes \mathbb{1} \\
 & \searrow \text{id}_M & \downarrow \mu & \swarrow \text{id}_M & \\
 & & M & &
 \end{array}$$

commute. The first diagram is the *associativity* relation $\mu \circ (\mu \otimes \text{id}_M) = \mu \circ (\text{id}_M \otimes \mu)$ and the second diagram is the *unit* relation $\text{id}_M = \mu \circ (\eta \otimes \text{id}_M) = \mu \circ (\text{id}_M \otimes \eta)$.

Dually, a *comonoid* object in \mathcal{C} is a triple (M, δ, ϵ) for an object $M \in \mathcal{C}$, a *comultiplication* map $\delta : M \rightarrow M \otimes M$ and a *counit* map $\epsilon : M \rightarrow \mathbb{1}$, satisfying the *coassociativity* relation

$$\begin{array}{ccccc}
 & & M \otimes M \otimes M & & \\
 & \nearrow \delta \otimes \text{id}_M & & \nwarrow \text{id}_M \otimes \delta & \\
 M \otimes M & & & & M \otimes M \\
 & \nwarrow \delta & & \nearrow \delta & \\
 & & M & &
 \end{array}$$

and *counit* relation

$$\begin{array}{ccccc}
 \mathbb{1} \otimes M & \xleftarrow{\epsilon \otimes \text{id}_M} & M \otimes M & \xrightarrow{\text{id}_M \otimes \epsilon} & M \otimes \mathbb{1} \\
 & \nwarrow \text{id}_M & \uparrow \delta & \nearrow \text{id}_M & \\
 & & M & &
 \end{array} .$$

Monoid objects generalise monoids, i.e. sets with an identity equipped with an associative binary operation.

Definition 2.3.2. A Frobenius object in \mathcal{C} is a quintuple $(A, \mu, \eta, \delta, \epsilon)$ such that (A, μ, η) is a monoid object, (A, δ, ϵ) is a comonoid object, and the maps satisfy the *Frobenius relations*

$$\begin{array}{ccccc}
 & & A \otimes A & & \\
 & \nwarrow \delta \otimes \text{id}_A & \downarrow \mu & \nearrow \text{id}_A \otimes \delta & \\
 A \otimes A \otimes A & & A & & A \otimes A \otimes A \\
 & \nwarrow \text{id}_A \otimes \mu & \downarrow \delta & \nearrow \mu \otimes \text{id}_A & \\
 & & A \otimes A & &
 \end{array} ,$$

that is $(\text{id}_A \otimes \mu) \circ (\delta \otimes \text{id}_A) = \delta \circ \mu = (\mu \otimes \text{id}_A) \circ (\text{id}_A \otimes \delta)$.

The maps and relations for a Frobenius object $(A, \mu, \eta, \delta, \epsilon)$ have a nice description with the diagrams given in [Section 2.1](#). The structure maps are drawn as

For the rest of this section, we only work with the Frobenius object A and $\mathbb{1}$, so we can identify the identity strand $\mathbb{1} = \text{id}_A$ so we can stop putting the label A . Diagrammatically, the associativity relation $\mu \circ (\mu \otimes \text{id}_M) = \mu \circ (\text{id}_M \otimes \mu)$ is

the coassociativity relation $(\delta \otimes \text{id}_A) \circ \delta = (\text{id}_A \otimes \delta) \circ \delta$ is

the unit relation $\text{id}_A = \mu \circ (\eta \otimes \text{id}_A) = \mu \circ (\text{id}_A \otimes \eta)$ is

the counit relation $\text{id}_A = (\epsilon \otimes \text{id}_A) \circ \delta = (\text{id}_A \otimes \epsilon) \circ \delta$ is

and the Frobenius relation $(\text{id}_A \otimes \mu) \circ (\delta \otimes \text{id}_A) = \delta \circ \mu = (\mu \otimes \text{id}_A) \circ (\text{id}_A \otimes \delta)$ is

If we stop labelling the functions and draw the structure maps as

then the relations become... [Talk about isotopy](#)

Maybe something about the (diagrammatic?) category \mathbf{Frob} , capturing the data of a Frobenius object

Chapter 3

One-colour Diagrammatics

3.1 One-colour Diagrammatic Hecke Category

The first one-colour diagrammatic we explore is the *one-colour (diagrammatic) Hecke category* $\mathcal{H}(S_2)$ for the symmetric group $S_2 = \langle s \mid s^2 = e \rangle$. At the end of this section, we see that this diagrammatic category is equivalent to the category of Soergel Bimodules under additive Karoubian closure.

Remark 3.1.1. All diagrammatics below and in [Chapter 4](#) can be defined in the language of planar algebras, without mentioning (monoidal) categories, e.g. in [\[Jon21\]](#). Nevertheless, we define them in the context of categories as we will see them as diagrammatic versions of important categories in representation theory.

What do we do about \mathbb{C} ? Do the theorems (at the end) apply over \mathbb{Z} or \mathbb{C} or both? If we define over \mathbb{Z} , how do we use it over \mathbb{C} for the next section?

Definition 3.1.2. The *one-colour (diagrammatic) Hecke category* $\mathcal{H}(S_2)$ is a \mathbb{Z} -linear monoidal category with the following presentation.

The objects are generated by taking formal tensor products of the non-identity element $s \in S_2$. We will write these objects as words, e.g. $s, ssss =: s^4, sssssss =: s^7$, where the tensor product is concatenation. The empty tensor product, i.e. the monoidal identity, will be denoted $\emptyset =: s^0$.

The morphisms are generated, up to isotopy, by univalent and trivalent vertices

(3.1.3)

that are maps $s \rightarrow \emptyset$ and $ss \rightarrow s$ respectively. Note that we put a large dot on univalent vertices to signify that the line stops abruptly and does not connect to the top. The composition of such diagrams is appropriate vertical stacking, and the tensor product is horizontal concatenation (without intersection). The free \mathbb{Z} -module structure on each morphism space $\text{Hom}(s^n, s^m)$ produces \mathbb{Z} -linear combinations of such diagrams.

Something about composition/tensor and addition commuting Then, composition or tensors with the zero morphism 0 result in 0. To abuse notation, the empty diagram $\emptyset \rightarrow \emptyset$ will be denoted \emptyset . The identity morphism in $\text{Hom}(s^n, s^n)$ is the diagram consisting of n (red) vertical lines

$$\begin{array}{c} | \\ | \\ \vdots \\ | \end{array}, \quad (3.1.4)$$

which we may identify with s^n .

Such diagrams are subject to the following local relations

$$\begin{array}{c} | \\ \text{---} \bullet \end{array} = \begin{array}{c} | \end{array}, \quad (3.1.5a)$$

$$\begin{array}{c} \diagup \\ | \\ \diagdown \end{array} = \begin{array}{c} \diagdown \\ | \\ \diagup \end{array}, \quad (3.1.5b)$$

$$\begin{array}{c} | \\ \bigcirc \\ | \end{array} = 0, \quad (3.1.5c)$$

$$\begin{array}{c} \bullet \\ | \\ \bullet \end{array} = 2 \begin{array}{c} \bullet \\ | \\ \bullet \end{array} - \begin{array}{c} | \\ \bullet \end{array}. \quad (3.1.5d)$$

Remark 3.1.6. The object s is a Frobenius object in $\mathcal{H}(S_2)$. The generators (3.1.3) and their horizontal reflections are the unit, multiplication, counit and comultiplication maps. The unit, associativity and Frobenius associativity axioms are satisfied by the relations (3.1.5a) and (3.1.5b).

Put a definition of frob object in intro

Example 3.1.7. Using the relations in (3.1.5) we can simplify the morphism in $\text{Hom}(ss, s)$,

$$\begin{array}{c} \bullet \quad \bullet \\ \diagdown \quad \diagup \\ | \\ \bullet \quad \bullet \\ \diagup \quad \diagdown \\ | \\ \bullet \quad \bullet \end{array} = \begin{array}{c} | \\ \diagdown \quad \diagup \\ | \\ \bullet \quad \bullet \end{array} = 2 \begin{array}{c} | \\ \diagdown \quad \diagup \\ | \\ \bullet \quad \bullet \end{array} - \begin{array}{c} | \\ \diagdown \quad \diagup \\ | \\ \bullet \quad \bullet \end{array}$$

$$= 2 \begin{array}{c} \bullet \\ | \\ \bullet \end{array} \begin{array}{c} | \\ | \\ | \end{array} \begin{array}{c} \bullet \\ | \\ \bullet \end{array} - \begin{array}{c} \bullet \\ | \\ \bullet \end{array} \begin{array}{c} \bullet \\ | \\ \bullet \end{array} \begin{array}{c} \bullet \\ | \\ \bullet \end{array}.$$

Add example of using frob associativity

The morphism space $\text{Hom}(s^n, s^m)$ has a left (or right) $\mathbb{Z}[\bullet]$ -basis called the *double leaves* basis, as described in [EW16]. To define this basis, we must first define morphisms known as *light leaves*.

To make use of the group structure of S_2 , we need to translate between words in $\mathcal{H}(S_2)$ and elements in S_2 . Let $\phi : (\text{ob}(\mathcal{H}(S_2)), \otimes) \rightarrow (S_2, *)$ be the monoid homomorphism¹ mapping $s \mapsto s$ and $\emptyset \mapsto 1$, and $\psi : S_2 \rightarrow \text{ob}(\mathcal{H}(S_2))$ be the function that maps $s \mapsto s$ and $1 \mapsto \emptyset$. **Should this be a definition?** The maps ϕ allows words $w = s^n$ to be seen as elements of S_2 , and ψ allows $1, s \in S_2$ to be seen as the objects $\emptyset, s \in \mathcal{H}(S_2)$. Clearly, $\phi\psi$ is the identity map on S_2 , and the map $\psi\phi : \mathcal{H}(S_2) \rightarrow \mathcal{H}(S_2)$ takes objects to one of \emptyset or s in $\mathcal{H}(S_2)$ by considering them as elements in S_2 .

Definition 3.1.8. (Subexpression for S_2) Given a word $w = s^n$, a *subexpression* e is a binary string of length n . We can *apply* a subexpression to produce an object $w(e) \in \mathcal{H}(S_2)$, which is w where terms corresponding to 0 in e are replaced with \emptyset . For $0 \leq i \leq n$, write $w(e, i)$ for the resultant object of the first i terms in e applied to the first i terms in w . Particularly $w(e, 0) = \emptyset$ and $w(e, n) = w(e)$.

For example, 0000, 0110 and 1011 are subexpressions of $s^4 = ssss$. Applying the third subexpression gives $ssss(1011) = s\emptyset ss = sss$ and $ssss(1011, 3) = sss(101) = s\emptyset s = \emptyset$, by strictness of the monoidal category. Here, each term of the subexpression is a decision to include or exclude the corresponding s in the word, where excluding an s amounts to tensoring with \emptyset .

For a word w and subexpression e , we label each term by U_0, U_1, D_0 or D_1 . The i -th term is labelled U_* if $\phi(w(e, i - 1)) = 1 \in S_2$, and labelled D_* if $\phi(w(e, i - 1)) = s \in S_2$. The label's subscript is the corresponding term in e .

Example 3.1.9. For the object $w = ssss$ and subexpression $e = 0101$, we find the labels as recorded in the following table.

Term i	1	2	3	4
Partial w	s	ss	sss	$ssss$
Partial e	0	01	010	0101
$w(e, i)$	\emptyset	$\emptyset s = s$	$\emptyset s \emptyset = s$	$\emptyset s \emptyset s = ss$
Labels	U_0	$U_0 U_1$	$U_0 U_1 D_0$	$U_0 U_1 D_0 D_1$

Definition 3.1.10. The *light leaf* $LL_{w,e} \in \text{Hom}(w, \psi\phi(w(e)))$ for a word w and subexpression e , is defined iteratively as follows. Let $LL_{\emptyset, \emptyset} = \emptyset$ be the empty diagram. Given $LL_{w',e'}$ and $i \in \{0, 1\}$, the light leaf $LL_{w's,e'i}$ is one of

¹A map that preserves the monoidal product and identity element.

$$\begin{array}{c} \boxed{LL_{w',e'}} \\ \vdots \\ \bullet \\ U_0 \end{array}, \begin{array}{c} \boxed{LL_{w',e'}} \\ \vdots \\ U_1 \end{array}, \begin{array}{c} \boxed{LL_{w',e'}} \\ \vdots \\ D_0 \end{array}, \begin{array}{c} \boxed{LL_{w',e'}} \\ \vdots \\ D_1 \end{array} \quad (3.1.11)$$

corresponding to the next label, where w' and e' are appropriate subwords² of w and e respectively.

Here, the codomain of a light leaf $LL_{w,e}$ is the object $\psi\phi(w(e))$. So if the next label is U_* then the codomain of $LL_{w',e'}$ is \emptyset , and when the next label is D_* the codomain of $LL_{w',e'}$ is s . This implies that the recursive definition is consistent.

Example 3.1.12. Following from [Example 3.1.9](#) for $w = ssss$ and $e = 0101$, we have labels $U_0U_1D_0D_1$ so the light leaf $LL_{w,e}$ is built as follows.

Definition 3.1.13. Let $\overline{LL}_{w,e}$ denote the vertical reflection of $LL_{w,e}$. The *double leaf* for words w, y in $\mathcal{H}(S_2)$ is a composition

$$\mathbb{L}_{f,e} := \overline{LL}_{y,f} \circ LL_{w,e} : w \rightarrow y$$

for subexpressions e of w and f of y such that $\psi\phi(w(e)) = \psi\phi(f(y))$.

Visually these are diagrams from w to y factoring through $\psi\phi(w(e)) = \psi\phi(f(y)) \in \{\emptyset, s\}$,

$$\begin{array}{c} y \\ \overline{LL}_{y,f} \\ \psi\phi(w(e)) = \psi\phi(f(y)) \\ LL_{w,e} \\ w \end{array}$$

Example 3.1.14. Let $w = ssss$ and $y = sss$. Let $e = 0111$ be a subexpression of w , and $f = 010$ be a subexpression of y . The corresponding light leaves are

$$LL_{w,e} = \begin{array}{c} \bullet \\ \vdots \\ U_0 \end{array} \begin{array}{c} \vdots \\ U_1 \end{array} \begin{array}{c} \vdots \\ D_1 \end{array} \begin{array}{c} \vdots \\ U_1 \end{array} \quad \text{and} \quad LL_{y,f} = \begin{array}{c} \bullet \\ \vdots \\ U_0 \end{array} \begin{array}{c} \vdots \\ U_1 \end{array} \begin{array}{c} \vdots \\ D_0 \end{array}$$

Then the double leaf $\mathbb{L}_{f,e} = \overline{LL}_{y,f} \circ LL_{w,e} : ssss \rightarrow sss$, factoring through s , is

$$\begin{array}{c} \overline{LL}_{y,f} \\ \text{---} \\ LL_{w,e} \end{array}$$

²A word with some letters removed.

Note that these double leaves have no floating diagrams such as $\textcolor{red}{\downarrow}$. In order for these double leaves to be a basis for a morphism space, we insert these floating diagrams by taking linear combinations as a left $\mathbb{Z}[\textcolor{red}{\downarrow}]$ -module, where the (left) $\textcolor{red}{\downarrow}$ -action is left concatenation by $\textcolor{red}{\downarrow}$. Since we can move barbells to the right via the relation (3.1.5d) and double leaves cut down the middle are double leaves factoring through \emptyset , we can equivalently act by $\mathbb{Z}[\textcolor{red}{\downarrow}]$ on the right. This leads us to the following theorem.

Theorem 3.1.15 (Elias-Williamson [EW16, Theorem 1.2]). *Given objects $w, y \in \mathcal{H}(S_2)$, let $\mathbb{LL}(w, y)$ be the collection of double leaves $\mathbb{LL}_{f,e}$ for subexpressions e of w and f of y , such that $\psi\phi(w(e)) = \psi\phi(y(f))$. Then $\mathbb{LL}(w, y)$ is a basis for $\text{Hom}(w, y)$ as a left (or right) $\mathbb{Z}[\textcolor{red}{\downarrow}]$ -module.*

A purely diagrammatic proof (of a more general theorem) can be found in [EW16].

Remark 3.1.16. The above light leaves and double leaves, introduced in [EW16], are diagrammatic analogues of Libedinsky’s construction in [Lib08].

The morphisms in this category can be graded such that the univalent vertices has degree 1 and trivalent vertices have degree -1 . The degree of a diagram is the sum of the degrees of the generators that appear in it. This induces a grading for the morphism spaces of $\mathcal{H}(S_2)$. Maybe mention what a grading is.

Put example

The double leaves bases allow us to show that the Karoubi envelope of $\mathcal{H}(S_2)$ is equivalent to the category of Soergel Bimodules \mathbb{SBim} over S_2 as monoidal categories.

Theorem 3.1.17 (Elias-Williamson [EW16, Theorem 6.30]). *The category $\text{Kar}_\oplus(\mathcal{H}(S_2))$ and the category of Soergel Bimodules \mathbb{SBim} over S_2 are equivalent as graded \mathbb{Z} -linear monoidal categories.*

The proof in [EW16] gives an equivalence of graded \mathbb{Z} -linear monoidal categories $\mathcal{H}(S_2) \cong \mathbb{BSBim}$ where \mathbb{BSBim} is the category of Bott-Samelson bimodules over S_2 . This was done by comparing the graded dimensions of morphism spaces using double leaves bases. Since $\text{Kar}_\oplus(\mathbb{BSBim}) \cong \mathbb{SBim}$ and Karoubi envelope preserves equivalences, we obtain $\text{Kar}_\oplus(\mathcal{H}(S_2)) \cong \mathbb{SBim}$.

3.2 Diagrammatic $\mathcal{O}_0(\mathfrak{sl}_2)$

A little bit about category \mathcal{O} , and our example of \mathfrak{sl}_2

For this section, our category of interest is \mathcal{O} for the semisimple Lie algebra $\mathfrak{sl}_2(\mathbb{C})$. A description of the category \mathcal{O} can be found in general in [Hum08, Sections 3.8–3.10] or in [Maz09, Section 5.2] for the case of $\mathfrak{sl}_2(\mathbb{C})$, however we will only give a brief overview. The category \mathcal{O} is a category of certain modules (or representations) over a semisimple Lie algebra. It is a direct sum of subcategories, where, in the case of \mathfrak{sl}_2 over \mathbb{C} , the non-trivial summands are equivalent as abelian categories to the subcategory \mathcal{O}_0 . Within this, we look to the full subcategory $\text{proj}(\mathcal{O}_0)$ of projective modules in \mathcal{O}_0 , which is in particular additive and contains all direct summands.

In [Soe90, Section 2.4], Soergel shows that the category \mathcal{O} , and hence the subcategory $\text{proj}(\mathcal{O}_0)$, is a Soergel module category, i.e. it has an action of the monoidal category $\mathbb{S}\text{Bim}$. By the equivalence in Theorem 3.1.17 we will view $\text{proj}(\mathcal{O})$ as a $\mathcal{H}(S_2)$ -module category, extending via the additive Karoubi envelope. Since $\mathcal{H}(S_2)$ is diagrammatic, this action allows us to describe $\text{proj}(\mathcal{O}_0)$ (thus essentially \mathcal{O}_0 and \mathcal{O}) diagrammatically.

Remark 3.2.1. We can pass from $\text{proj}(\mathcal{O}_0)$ to \mathcal{O}_0 by observing that $K^b(\text{proj}(\mathcal{O}_0))$ is equivalent to $D^b(\mathcal{O}_0)$ as graded \mathbb{Z} -linear Should this be \mathbb{C} ? monoidal triangulated categories. This is a standard trick in the field, for example see the introduction of [RW18]³. However for our purposes it is not important to understand how this works.

Remark 3.2.2. For $\mathfrak{sl}_2(\mathbb{C})$, the morphism spaces in $\text{proj}(\mathcal{O}_0)$ are \mathbb{C} -modules so the diagrammatic category $\mathcal{H}(S_2)$ from Section 3.1 must be extended from \mathbb{Z} to \mathbb{C} . Formally this is just tensoring the morphism spaces on the left by the \mathbb{C} - \mathbb{Z} -bimodule \mathbb{C} , where the right action is induced by the inclusion $\mathbb{Z} \subset \mathbb{C}$. For the remainder of this section, $\mathcal{H}(S_2)$ will refer to this \mathbb{C} -linear extension. Note that the above process does little to the category. In particular, double leaves in $\mathcal{H}(S_2)$ become $\mathbb{C}[\text{!}]$ -bases⁴ for the morphisms and the equivalence in Theorem 3.1.17 still holds.

Definition 3.2.3. Let $\mathcal{DO}_0(\mathfrak{sl}_2)$ be the \mathbb{C} -linear (Define this in background) left $\mathcal{H}(S_2)$ -module category with elements generated (Define what this means.) by the monoidal identity \emptyset of $\mathcal{H}(S_2)$ and morphisms generated by the empty diagram \emptyset . The action of $\mathcal{H}(S_2)$ on the left is left concatenation for both objects and morphisms. In addition to the relations from $\mathcal{H}(S_2)$, the morphisms have one new relation in which diagrams collapse to 0 when there are barbells on the right. To depict this we add a wall on the right of the diagram, i.e. embedding the diagrams in the one-sided strip $[0, 1] \times \mathbb{R}_{\geq 0}$ instead of in the double-sided strip $[0, 1] \times \mathbb{R}$. For example a morphism may be

We impose the relation that diagrams are related to the wall by

$$\text{!} \text{ } \text{wall} = 0. \quad (3.2.4)$$

In this section we may write \mathcal{DO}_0 for this category. Talk about the \mathbb{C} -linear structure and how that works.

³A self-contained summary of how diagrammatic categories can be related to abelian categories.

⁴It is easy to see that double leaves tensored with $1 \in \mathbb{C}$ on the left form a basis.

Example 3.2.5. Using the new relation (3.2.4), we can further simplify the morphism in Example (3.1.7) by

$$\begin{aligned}
& \text{Diagram 1} = 2 \text{ Diagram 2} - \text{Diagram 3} \\
& = 2 \left(2 \text{ Diagram 4} - \text{Diagram 5} \right) - 0 \\
& = 4 \text{ Diagram 6} .
\end{aligned}$$

The objects of this category are identical to objects in $\mathcal{H}(S_2)$ and the morphisms are the same modulo the wall relation (3.2.4). A natural question to ask is whether double leaves still form bases for the morphism spaces here. Notice that double leaves appear in \mathcal{DO}_0 by acting on \emptyset by double leaves in $\mathcal{H}(S_2)$. All morphisms in \mathcal{DO}_0 are morphisms in $\mathcal{H}(S_2)$ so they can be written as $\mathbb{C}[\bullet]$ -linear combinations of double leaves, though some have collapsed to 0. Thus double leaves span the morphism spaces of \mathcal{DO}_0 as (left) $\mathbb{C}[\bullet]$ -modules. However they may not be linearly independent as neither left nor right modules. For example, any pair of double leaves that factor through \emptyset become 0 when multiplied by \bullet on either side (by shifting the barbell to the right). Although double leaves are not always a basis for its respective morphism space as $\mathbb{C}[\bullet]$ -modules, it turns out they are a basis over \mathbb{C} .

Lemma 3.2.6. *Let $\pi : \text{mor}(\mathcal{H}(S_2)) \rightarrow \text{mor}(\mathcal{DO}_0)$ be the projection map which takes a morphism f to the result of its action on \emptyset . Then the image $\pi(\mathbb{LL}(w, y))$ is a basis for $\text{Hom}_{\mathcal{DO}_0}(w, y)$ as a \mathbb{C} -module.*

Proof. We consider morphisms $\text{Hom}(w, y)$ in \mathcal{DO}_0 for fixed objects w, y , and write $\mathbb{LL} := \pi(\mathbb{LL}(w, y))$ for the set of double leaves in \mathcal{DO}_0 . Any diagram in \mathcal{DO}_0 can be written as a \mathbb{C} -linear combination of morphisms without floating diagrams by simplifying them to barbells, pulling them to the right and using (3.2.4). The diagrams \mathbb{LL} span morphisms without floating components as a \mathbb{C} -module. This can be observed by writing morphisms as a linear combination of double leaves, by (3.1.15) with the right action, then applying π and (3.2.4). Since the barbell-wall relation (3.2.4) has no effect on \mathbb{C} -linear combinations of \mathbb{LL} , it follows from linear independence over $\mathbb{C}[\bullet]$ that they are linearly independent over \mathbb{C} in \mathcal{DO}_0 . *Check the proof.* \square

Maybe put this next bit in section 3.1

Say more about what this is, and why we say it here

Lemma 3.2.7. *In the additive closure **Do we need more?** of $\mathcal{H}(S_2)$ **Not this! Morphisms need to be over a field!** we have an explicit isomorphisms $s \otimes s \cong s \oplus s$, as detailed in the proof.*

Proof. In $\mathcal{H}(S_2)$ we have the relation

$$\begin{aligned}
 \begin{array}{|c|} \hline \\ \hline \end{array} \begin{array}{|c|} \hline \\ \hline \end{array} &= \begin{array}{|c|} \hline \bullet \quad \bullet \\ \hline \end{array} \\
 &= \frac{1}{2} \begin{array}{c} \diagup \quad \diagdown \\ \bullet \quad \bullet \\ \diagdown \quad \diagup \end{array} + \frac{1}{2} \begin{array}{c} \diagdown \quad \diagup \\ \bullet \quad \bullet \\ \diagup \quad \diagdown \end{array} \\
 &= \frac{1}{2} \begin{array}{c} \bullet \quad \bullet \\ \diagdown \quad \diagup \\ \diagup \quad \diagdown \end{array} + \frac{1}{2} \begin{array}{c} \diagdown \quad \diagup \\ \bullet \quad \bullet \\ \diagup \quad \diagdown \end{array} .
 \end{aligned} \tag{3.2.8}$$

This implies we have maps

$$\begin{pmatrix} \frac{1}{2} \begin{array}{c} \diagup \quad \diagdown \\ \bullet \quad \bullet \\ \diagdown \quad \diagup \end{array} \\ \frac{1}{2} \begin{array}{c} \bullet \quad \bullet \\ \diagdown \quad \diagup \\ \diagup \quad \diagdown \end{array} \end{pmatrix} : ss \rightarrow s \oplus s \text{ and } \begin{pmatrix} \begin{array}{c} \bullet \quad \bullet \\ \diagdown \quad \diagup \end{array} \quad \begin{array}{c} \diagdown \quad \diagup \\ \bullet \quad \bullet \\ \diagup \quad \diagdown \end{array} \end{pmatrix} : s \oplus s \rightarrow ss.$$

It follows from (3.1.5d), (3.1.5c) and the above calculation (3.2.8), that these maps are inverses. **Maybe put the inverse calculation here.** \square

Before giving the main theorem, **(Reword this, this may be wrong)** we provide a useful description of $\text{proj}(\mathcal{O}_0(\mathfrak{sl}_2))$. This can be found in general in [Hum08, Sections 3.8–3.10], or in [Maz09, Section 5.2] for the specific case of \mathfrak{sl}_2 . The main category of interest is \mathcal{O} , of modules over semisimple Lie algebras satisfying certain finiteness conditions. The category \mathcal{O} is a direct sum of subcategories, and in the case of \mathfrak{sl}_2 , all non-trivial summands in this direct sum are equivalent to \mathcal{O}_0 as **Check:** abelian categories. The category $\text{proj}(\mathcal{O}_0)$ is a full subcategory of \mathcal{O}_0 containing only projective modules, which is in particular additive and contains all direct summands.

(Reword this) The following result is essentially due to Soergel [Soe90, Endomorphismsatz 7, Struktursatz 9 and Section 2.4] (see also [Soe98]) but was not originally formulated as such. The key arguments are in [Soe90] so we attribute this theorem to Soergel.

Be clear that I don't understand category \mathcal{O} very well.

Theorem 3.2.9 (Soergel, [Soe90, Endomorphismsatz 7, Struktursatz 9 and Section 2.4]). *The diagrammatic category $\text{Kar}_\oplus(\mathcal{DO}_0(\mathfrak{sl}_2))$ and $\text{proj}(\mathcal{O}_0(\mathfrak{sl}_2))$ are equivalent as \mathbb{C} -linear $\mathcal{H}(S_2)$ -module categories.*

Check all of this & Put precise references

Clean up the differences between $\text{proj } \mathcal{O}_0$, \mathcal{O}_0 , \mathcal{O} .

Maybe write description as a soergel module outside the proof

Proof. As a shorthand, we write $\text{proj}(\mathcal{O}_0)$ for $\text{proj}(\mathcal{O}_0(\mathfrak{sl}_2))$. The work of Soergel in [Soe90, Section 2.4] shows that $\text{proj}(\mathcal{O}_0)$ is a Soergel module, i.e. it has a left action of the category of Soergel bimodules defined by applications of the translation functors $\Theta_\emptyset, \Theta_s \in \text{End}(\mathcal{O})$ (corresponding to elements in S_2). Explains what this means, how its related to the $\mathcal{H}(S_2)$ module category We will construct a functor that will map faithfully into a full subcategory of $\text{proj}(\mathcal{O}_0)$, which will become the whole projective category under the additive Karoubi envelope. This mimics the strategy in the proof for Theorem 3.1.17 in the previous section.

Define the functor $F : \mathcal{DO}_0 \rightarrow \text{proj}(\mathcal{O}_0)$ that sends the empty object \emptyset to the trivial module $P(\emptyset)$, and the Soergel module action corresponding to s to the translation functor Θ_s . Then the object s maps to $\Theta_s(P(\emptyset)) =: P(s)$, and for example s^3 maps to $\Theta_s^3(P(\emptyset)) = \Theta_s \Theta_s \Theta_s(P(\emptyset))$. In order for F to be functorial, it must map identity diagrams $s^n \rightarrow s^n$ to $\text{id}_{\Theta_s^n(P(\emptyset))}$. On non-identity maps, we let $F(\downarrow) = i$ be the inclusion $P(\emptyset) \rightarrow P(s)$ and $F(\uparrow) = p$ be the projection $P(s) \rightarrow P(\emptyset)$. The mapping of F is depicted by the following picture.

Say more here Now [Maz09, Proposition 5.90] shows that there is a natural isomorphism $\Theta_s \Theta_s \cong \Theta_s \oplus \Theta_s$ analogous to the isomorphism $s \otimes s \cong s \oplus s$ given in the proof of Lemma 3.2.7. We obtain the trivalent vertices by appropriately composing these isomorphisms with the projection $s \oplus s \rightarrow s$ and inclusion $s \rightarrow s \oplus s$. Extending by linearity, the univalent vertices and trivalent vertices generate the domain of F , thus this description completely determines the image of F .

From classical results e.g. [Maz09, Proposition 5.84 and Lemma 5.87], it follows that Θ_s is a Frobenius object in the category of endofunctors of \mathcal{O} . Then there are unit, counit, multiplication and comultiplication natural transformations satisfying coherence relations in the Frobenius object structure. Applying these to $P(\emptyset)$ result in the same relations in $\text{proj}(\mathcal{O}_0)$ for $P(\emptyset), P(s)$ and $\Theta_s^2(P(\emptyset))$. Note that the projection and inclusion maps above are exactly the unit and counit of Θ_s evaluated at $P(\emptyset)$, and the trivalent vertices provided by Lemma 3.2.7 are exactly the multiplication and comultiplication maps. Furthermore, [Soe90, Section 2.4] shows that $p \circ i = 0$ in $\text{proj}(\mathcal{O}_0)$ which

is analogous **Wheres the wall?** to the barbell-wall relation (3.2.4). Since all the relations in \mathcal{DO}_0 are preserved by F and by construction F preserves \mathbb{C} -linearity and the Soergel module structure in [Soe90], we conclude that F is well defined as a functor between \mathbb{C} -linear $\mathcal{H}(S_2)$ -module categories.

We now prove that F is fully faithful. It follows from **Lemma 3.2.7** and the description of $P(\emptyset)$ and $P(s)$ in [Maz09, Section 5.2] that the image of \uparrow and \downarrow generate all morphisms of the form $\Theta_s^n(P(\emptyset)) \rightarrow \Theta_s^m(P(\emptyset))$. Hence F is full. Now the mapping of F on all morphism spaces are determined by those depicted in the above picture. So, for faithfulness, it suffices to compare the \mathbb{C} -dimensions of morphism spaces between objects shown in the picture. By **Lemma 3.2.6**, $\text{Hom}(\emptyset, \emptyset)$ has a basis $\{\emptyset = \text{id}_\emptyset\}$, $\text{Hom}(s, \emptyset)$ has a basis $\{\uparrow\}$, $\text{Hom}(\emptyset, s)$ has a basis $\{\downarrow\}$, and $\text{Hom}(s, s)$ has a basis $\{\text{id}_s, \downarrow \circ \uparrow\}$. The bases for the corresponding morphism spaces in $\text{proj } \mathcal{O}_0$ are exactly those in the image **Ref? - that these are actually the bases of the hom spaces**, so these dimensions coincide. Therefore F is fully faithful.

The objects in $\text{proj}(\mathcal{O}_0)$ are all direct sums and direct summands of the elements $\Theta_s^n(P(\emptyset))$ for non-negative integers n , so the additive Karoubi envelope induces an equivalence $\text{Kar}_\oplus(\mathcal{DO}_0) \cong \text{proj}(\mathcal{O}_0)$ as \mathbb{C} -linear left $\mathcal{H}(S_2)$ -module categories. **Should this be $\text{Kar}_\oplus(\mathcal{H}(S_2))$** \square

Maybe talk about Soergel modules and $\mathcal{H}(S_2)$ -modules vs $\text{Kar}_\oplus(\mathcal{H}(S_2))$ -modules

Remark 3.2.10. The morphisms spaces in \mathcal{DO}_0 are graded by the same grading as $\mathcal{H}(S_2)$ in **Section 3.1**. The equivalence $\text{Kar}_\oplus(\mathcal{DO}_0) \cong \text{proj}(\mathcal{O}_0)$ includes a grading of morphisms in $\text{proj}(\mathcal{O}_0)$ and hence a grading morphisms of \mathcal{O} , which is otherwise ungraded. **Check**

Chapter 4

Two-colour Diagrammatics

The previous chapter had its focus on the symmetric group generated by one element S_2 , which brought about one-colour diagrammatics. We shift our attention to a more complex example by adding an extra generator, that is, another colour. In particular, we consider the case for the affine symmetric group on two elements $\tilde{S}_2 = \langle s, t \mid s^2 = t^2 = 1 \rangle$.

[Refine this](#)

4.1 Two-colour Diagrammatic Hecke Category

Corresponding to \tilde{S}_2 , we define the two-colour (diagrammatic) Hecke category $\mathcal{H}(\tilde{S}_2)$. This is a (strict) \mathbb{C} -linear monoidal category given by the following isotopy presentation.

Objects in $\mathcal{H}(\tilde{S}_2)$ are generated by formal tensor products of the non-identity elements $s, t \in \tilde{S}_2$. As before, we write objects as words such as $sstttst =: s^2t^3st$ where the tensor product is concatenation, and associate the colour **red** to s and **blue** to t . The empty word is the monoidal identity, which we write as \emptyset .

The morphisms are generated by the univalent and trivalent vertices

$$\begin{array}{c} \bullet \\ | \end{array}, \quad \begin{array}{c} | \\ \diagup \quad \diagdown \end{array}, \quad \begin{array}{c} \bullet \\ | \end{array}, \quad \begin{array}{c} | \\ \diagup \quad \diagdown \end{array} \quad (4.1.1)$$

that are maps $s \rightarrow \emptyset$, $ss \rightarrow s$, $t \rightarrow \emptyset$ and $tt \rightarrow t$ respectively. As in the one-colour case, tensor product is horizontal concatenation, composition is appropriate vertical stacking, and we denote the empty diagram $\emptyset \rightarrow \emptyset$ by \emptyset . For each colour, these diagrams have the one-colour relations given by (3.1.5). Since we have two colours now, we also need to describe how the colours interact. This is given by the *two-colour relation*

$$\begin{array}{c} \bullet \\ | \end{array} \begin{array}{c} | \\ | \end{array} = \begin{array}{c} \bullet \\ | \end{array} \begin{array}{c} | \\ | \end{array} + \begin{array}{c} \bullet \\ | \end{array} \begin{array}{c} | \\ | \end{array} - \begin{array}{c} \bullet \\ | \end{array} \begin{array}{c} | \\ | \end{array} \quad (4.1.2)$$

and with red and blue swapped.

Example 4.1.3. Using the one-colour and two-colour relations on the following morphism in $\text{Hom}(ttsts, tst)$ we have The last line can be simplified if tensor product is \mathbb{Z} -bilinear

$$\begin{aligned}
& \text{Morphism 1} = \text{Morphism 2} \\
& = 2 \cdot \text{Morphism 3} - \text{Morphism 4} \\
& = 2 \cdot \text{Morphism 5} - \left(\text{Morphism 6} + \text{Morphism 7} - \text{Morphism 8} \right) \\
& = 2 \cdot \text{Morphism 9} - \text{Morphism 10} - 2 \cdot \text{Morphism 11} + 2 \cdot \text{Morphism 12}.
\end{aligned}$$

Remark 4.1.4. Notice that the red and blue lines never cross as no generators that allow crossings. This is a consequence of working over affine S_2 in which the generators s and t have no relation. Mention example of crossing and S_3 .

Definition 4.1.5. For a group with a presentation in terms of generators and relations, the *length* of a product of generators is the number of generators in the product. We say that a product of generators is *reduced* if it's length cannot be shortened with relations.

In \tilde{S}_2 products can be shortened by the relation $s^2 = t^2 = 1$. For instance, $sttsts$ is not reduced because it is equal to ts which is reduced. Notice that for \tilde{S}_2 each element can be written uniquely as a reduced product of generators. This is true since otherwise we have two distinct reduced products for the same element in \tilde{S}_2 so they must be related by $s^2 = t^2$. This means they can be reduced further by $s^2 = t^2 = 1$, which contradicts minimality of their length. Note that the reduced products in \tilde{S}_2 are either the identity or alternating products of s and t .

Notice that there is a notational similarity between products in the group and words in $\mathcal{H}(\tilde{S}_2)$. This motivates the following definitions. Let $\phi : (\text{ob}(\mathcal{H}(\tilde{S}_2)), \otimes) \rightarrow (\tilde{S}_2, *)$ be the monoid homomorphism mapping $\emptyset \mapsto 1$, $s \mapsto s$ and $t \mapsto t$. Also define the function $\psi : \tilde{S}_2 \rightarrow \text{ob}(\mathcal{H}(\tilde{S}_2))$ to map elements $x \in \tilde{S}_2$ to the tensor product of s and t in $\mathcal{H}(\tilde{S}_2)$ corresponding to the reduced product of x in \tilde{S}_2 . This is well defined because reduced products are unique and two different reduced products cannot equal the same element of \tilde{S}_2 . Note that the image $\psi(\tilde{S}_2)$ is the set containing \emptyset and words of alternating s and t . The composition $\psi\phi : \mathcal{H}(\tilde{S}_2) \rightarrow \mathcal{H}(\tilde{S}_2)$ maps words w to the tensor of s and t corresponding to the reduced product of $\phi(w)$, and $\phi\psi$ is the identity map on \tilde{S}_2 .

The following definition is a more general version of Definition 3.1.8.

Definition 4.1.6 (Subexpression). Given a word w of length n , a *subexpression* e is a binary string of length n . A subexpression can be *applied* to produce an word $w(e)$, which is w where terms corresponding to 0 in e are replaced with \emptyset . For $1 \leq i \leq n$, we write $w(e, i)$ for the result of the first i terms of e applied to the first i terms in w . Particularly $w(e, 0) = \emptyset$ and $w(e, n) = w(e)$.

For example, in $\mathcal{H}(\tilde{S}_2)$, if $w = sttts$ and $e = 11001$ then $w(e) = st\emptyset\emptyset s = sts$ and $w(e, 3) = sts(110) = st\emptyset = st$ in $\mathcal{H}(\tilde{S}_2)$.

Let the *length* of a word be the number of generators in its tensor product. As before, given an object w and a subexpression e of w , we label each of the n terms by one of U_0, U_1, D_0, D_1 . Let $i \geq 0$, and write x for the i -th term of w . We label the i -th term U_* if $\psi\phi(w(e, i-1) \otimes x)$ is longer than $\psi\phi(w(e, i-1))$. In other words we write U_* if the next term of w will make $\psi\phi$ applied to the partially evaluated subexpression longer, regardless of the i -term of e . We label D_* if $\psi\phi(w(e, i-1) \otimes x)$ is longer than $\psi\phi(w(e, i-1))$. The label's subscript is the i -th term of e . Note that this construction is well defined because $\psi\phi(w(e, i-1) \otimes x) = \psi(\phi(w(e, i-1)) * \phi(x)) = \psi(\phi(w(e, i-1)) * x)$ is always either longer or shorter, since the last element of the reduced product is either the same as x or different. When they are the same, the word is shorter via $s^2 = t^2 = 1$, and when they are different it is longer as no relations can make it shorter.

Remark 4.1.7. This description of the labels (via. reduced products) is more akin to the definition for general Coxeter groups than in [Section 3.1](#).

Example 4.1.8. Consider the word $w = sttst$ and subexpression $e = 10011$. The labels can be constructed as in the following table.

Term i	1	2	3	4	5
Partial w	s	st	stt	$stts$	$sttst$
Partial e	1	10	100	1001	10011
$w(e, i)$	s	$s\emptyset$	$s\emptyset\emptyset = s$	$s\emptyset\emptyset s = ss$	$s\emptyset\emptyset st = sst$
Labels	U_1	U_1U_0	$U_1U_0U_0$	$U_1U_0U_0D_1$	$U_1U_0U_0D_1U_1$

Definition 4.1.9. The *light leaf* $LL_{w,e} \in \text{Hom}(w, \psi\phi(w(e)))$ for a word w and a subexpression e is defined iteratively as follows. Let $LL_{\emptyset, \emptyset} = \emptyset$ be the empty diagram. Given appropriate subwords w' and e' of w and e respectively, and if the next terms are x in w and i in e , the light leaf $LL_{w',e',i}$ is one of

$$\begin{array}{c} \begin{array}{|c|} \hline \dots \\ \hline \end{array} \\ \begin{array}{|c|} \hline LL_{w',e'} \\ \hline \end{array} \\ \begin{array}{|c|} \hline \dots \\ \hline \end{array} \end{array} \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} U_0, \begin{array}{c} \begin{array}{|c|} \hline \dots \\ \hline \end{array} \\ \begin{array}{|c|} \hline LL_{w',e'} \\ \hline \end{array} \\ \begin{array}{|c|} \hline \dots \\ \hline \end{array} \end{array} \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} U_1, \begin{array}{c} \begin{array}{|c|} \hline \dots \\ \hline \end{array} \\ \begin{array}{|c|} \hline LL_{w',e'} \\ \hline \end{array} \\ \begin{array}{|c|} \hline \dots \\ \hline \end{array} \end{array} \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} D_0, \begin{array}{c} \begin{array}{|c|} \hline \dots \\ \hline \end{array} \\ \begin{array}{|c|} \hline LL_{w',e'} \\ \hline \end{array} \\ \begin{array}{|c|} \hline \dots \\ \hline \end{array} \end{array} \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} D_1
\end{array} \quad (4.1.10)$$

corresponding to the next label. The **purple** strands are **red** if $x = s$ and **blue** if $x = t$.

Notice that the codomain of a light leaf $LL_{w,e}$ is the object $\psi\phi(w(e))$. So if the next label is U_* then the codomain of $LL_{w',e'}$ does not end with the colour corresponding

to x , and if the next label is D_* the codomain of $LL_{w',e'}$ ends with a strand with the colour corresponding to x . This implies the recursive definition in the diagram above is consistent. Note that in the case of D_* , one of the black strands in the domain of $LL_{w',e'}$ must have the colour of x in order for the colour to appear in its codomain.

Example 4.1.11. Following from [Example 4.1.8](#), with $w = sttst$, $e = 10011$ and labels $U_1U_0U_0D_1U_1$, the light leaf $LL_{w,e}$ is build as follows.

We can define double leaves exactly as we did in [Definition 3.1.13](#).

Definition 4.1.12. Let $\overline{LL}_{w,e}$ denote the vertical reflection of $LL_{w,e}$. The *double leaf* for words w, y in $\mathcal{H}(\tilde{S}_2)$ is a composition

$$\mathbb{L}_{f,e} := \overline{LL}_{y,f} \circ LL_{w,e} : w \rightarrow y$$

for subexpressions e of w and f of y such that $\psi\phi(w(e)) = \psi\phi(f(y))$.

Diagrammatically these are morphisms from w to y factoring through $\psi\phi(w(e)) = \psi\phi(f(y)) \in \psi(\tilde{S}_2)$,

$$\begin{array}{c} \text{ } y \\ \swarrow \quad \searrow \\ \overline{LL}_{y,f} \\ \swarrow \quad \searrow \\ \text{ } w \end{array} \quad \psi\phi(w(e)) = \psi\phi(f(y)) .$$

Example 4.1.13. Let $w = sst$ with the subexpression $e = 101$ and $y = tstst$ with the subexpression $f = 01001$. The corresponding light leaves are

$$LL_{w,e} = \begin{array}{c} \text{ } \\ \text{ } \\ \text{ } \end{array} \quad \text{and} \quad LL_{y,f} = \begin{array}{c} \text{ } \\ \text{ } \\ \text{ } \end{array} .$$

$U_1 \ D_0 \ U_1$ $U_0 \ U_1 \ U_0 \ D_0 \ U_1$

Then the double leaf $\mathbb{L}_{f,e} = \overline{LL}_{y,f} \circ LL_{w,e} : sst \rightarrow tstst$, factoring through st , is

$$\begin{array}{c} \overline{LL}_{y,f} \\ \text{ } \\ LL_{w,e} \end{array} .$$

As with the one-colour case, the set of double leaves $\mathbb{L}(w, y)$ from words w to y in $\mathcal{H}(\tilde{S}_2)$ form a basis for $\text{Hom}(w, y)$ over $\mathbb{Z}[\bullet, \bullet]$. The Hom spaces are graded such that the univalent vertices have degree 1 and trivalent vertices have degree -1 for either colour. Finally we have a similar theorem to [Theorem 3.1.17](#) for \tilde{S}_2 .

Remark 4.1.14. The construction of the diagrammatic Hecke category, light leaves, [Theorem 3.1.15](#) and [Theorem 3.1.17](#) all generalise to general Coxeter groups. The details are found in [\[EW16\]](#).

4.2 Diagrammatic $\text{Tilt}(\mathfrak{sl}_2)$

Something something about Tilt

Definition 4.2.1. Let $\mathcal{DT}(\mathfrak{sl}_2)$ be the \mathbb{C} -linear left $\mathcal{H}(\tilde{S}_2)$ -module category with elements generated by the monoidal identity \emptyset of $\mathcal{H}(\tilde{S}_2)$, and morphisms generated by the empty diagram \emptyset . The action of $\mathcal{H}(\tilde{S}_2)$ on the left is left concatenation for objects and morphisms. The relations on diagrams in $\mathcal{H}(\tilde{S}_2)$ follow through to diagrams in $\mathcal{DT}(\mathfrak{sl}_2)$. Additionally, we imagine a wall on the right of diagrams and impose the wall-annihilation relations

$$\begin{array}{c} \bullet \\ \text{---} \\ \bullet \end{array} \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} = \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} = 0. \quad (4.2.2)$$

In this section we just write \mathcal{DT} for this category.

Example 4.2.3. The morphism in [Example 4.1.3](#) collapses to 0 because all the diagrams have either blue or barbell on the right.

Another example clarifying 'blue on the right'
